Background: This study aims to identify interventions used to reduce medication regimen complexity and to assess their impact on medication adherence and clinical outcomes.

Methods: A literature search was conducted using pre-defined search terms in three scientific databases, including ScienceDirect, ProQuest and MEDLINE. Original research articles published in English between 2009 and 2020 that assessed the impact of medication regimen simplification on medication adherence in patients with long-term medical conditions were eligible for inclusion. Review articles, meta-analysis studies and conference proceedings were excluded. Data charting was done in an iterative process using a study-specific extraction form.

Results: Of the 684 studies identified through initial searches, 17 studies were included in the review. Nine studies involved simplification of medication regimen related to HIV, while three studies focused on patients with diabetes with or without coronary artery disease. The remaining five studies included medications used among elderly patients or medications related to hypertension, psychiatric disorders, glaucoma and kidney diseases. Three medication regimen simplification strategies were identified; fixed-dose combination (n = 7), once-daily dosing (n = 4) and the combination of both fixed-dose and once-daily dosing (n = 6). Overall, most of the regimen simplification strategies (14 out of 17) were found to be useful in improving medication adherence. There was no assessment of clinical outcomes in four out of 17 studies. Furthermore, more than half of the studies that assessed clinical outcomes did not show any additional impact on clinical outcomes.

Conclusion: The findings suggest that there was an equal utilization of the three main approaches of regimen simplifications; fixed-dose combination, once-daily dosing and a combination of both. Overall, most of the regimen simplification strategies were found to be effective in improving medication adherence. However, the associated improvement in medication adherence did not extend to improvement in the clinical outcomes.

Keywords: medication adherence, regimen simplification, clinical outcomes, review

Introduction

Non-adherence to prescribed medications has generally been accepted as a barrier to the effectiveness of prescription treatment in the management of long-term medical conditions.¹ Non-adherence to prescribed medications is prevalent among patients on long-term therapeutic plan and is associated with an increased risk of hospitalization and mortality risks.² Medication regimen complexity has been identified as one of the significant contributors to the prevalence of non-adherence.³ The number and

frequency of daily prescribed medications are among the typical elements of assessing the complexity of a prescribed regimen.⁴ Regimen complexity is commonly seen among patients with long-term therapeutic needs for conditions such as HIV, diabetes, hypertension, and asthma.^{5–8}

Additionally, complex regimens are common in the ageing population due to the prevalence of multiple comorbidities that consequently increase the need for polypharmacy.⁹ Furthermore, frequent hospitalizations lead to changes in the drug therapy regimen, particularly post-hospital discharge, which at times becomes more complex due to the initiation of newly prescribed medicines.¹⁰ Furthermore, an Italian study that assessed the association of regimen complexity with the risk of medication non-adherence suggested that regimen complexity had an independent association with the relative non-adherence risk.¹¹ Consequently, it has been reported that the interventions to reduce regimen complexity are sought to have a potential impact on the level of medication adherence.¹²

Medication regimen simplification is one of the viable strategies that can be employed to reduce the regimen complexity by minimizing the number of prescribed medications through interventions such as the fixed-dose combination (FDC).¹³ Another approach to regimen simplification focuses on reducing the frequency of the prescribed medications to a once-daily regimen where feasible.¹⁴ However, little has been known about the characteristics and effectiveness of the regimen simplifications implemented in clinical practice. This review, therefore, aims to assess the impact of medication regimen simplification strategies on medication adherence as well as to investigate their associated impact on clinical outcomes in patients with long-term medical conditions. Furthermore, it aims to characterize the types of studies based on the study population and prescribed medications that have been considered as part of regimen simplification interventions.

Methods

Search Strategy and Identification of the Studies

Three scholarly databases, ScienceDirect, ProQuest, and MEDLINE, were searched to identify potentially relevant studies. The search terms used were “Medication simplification AND adherence OR compliance” or “Regimen simplification AND adherence OR compliance”. Besides,

terms related to interventions to reduce medication regimen complexity were also reviewed for the possibility to be included only if the main intervention was regimen simplification. Original research articles that have been published between 2009 and 2020 and reported the implementation of regimen simplification strategies on adult patients with medication regimen complexity were included. The searches were limited to the last ten years to provide a review of the most recently published evidence. Only the studies that were measuring patients' adherence following medication regimen simplification were considered. Meanwhile, studies that were only measuring patients' satisfaction or acceptance based on regimen simplification were excluded. Furthermore, review articles, meta-analysis, book chapters and conference proceedings were excluded. The flowchart of the selection of the studies is presented in Figure 1.

Study Selection and Data Extraction

Two independent reviewers reviewed the studies based on titles and abstracts following the removal of duplicates. The eligible studies were identified and retrieved at full-text to consider them for inclusion. A series of meetings, in the beginning, at the middle and end of the data extraction process was conducted to ensure consistency. Any differences were resolved by the inclusion of a third reviewer. Data were extracted from the selected studies in two stages. The first stage collected information regarding the main study elements, which are the author's name, country, year, study design, study population, and study objectives. The second stage extracted information on the implemented simplification strategy and outcome measures for adherence and clinical outcomes. For each of the selected studies, the rationale for simplifying the medication regimen was identified. Furthermore, the impact of regimen simplification on the outcome measures was extracted. A descriptive analysis of the extracted data was performed. Reporting of the key findings was carried out in a consistent pattern with the investigated regimen simplification strategies and outcome measures. Further summarization of the adopted approach for simplification, methods of measuring medication adherence and clinical outcomes and the overall impact of the implemented regimen simplifications were provided.

Results

Of the 684 studies identified through the searches, a total of 17 studies were selected and included in this review. Nine

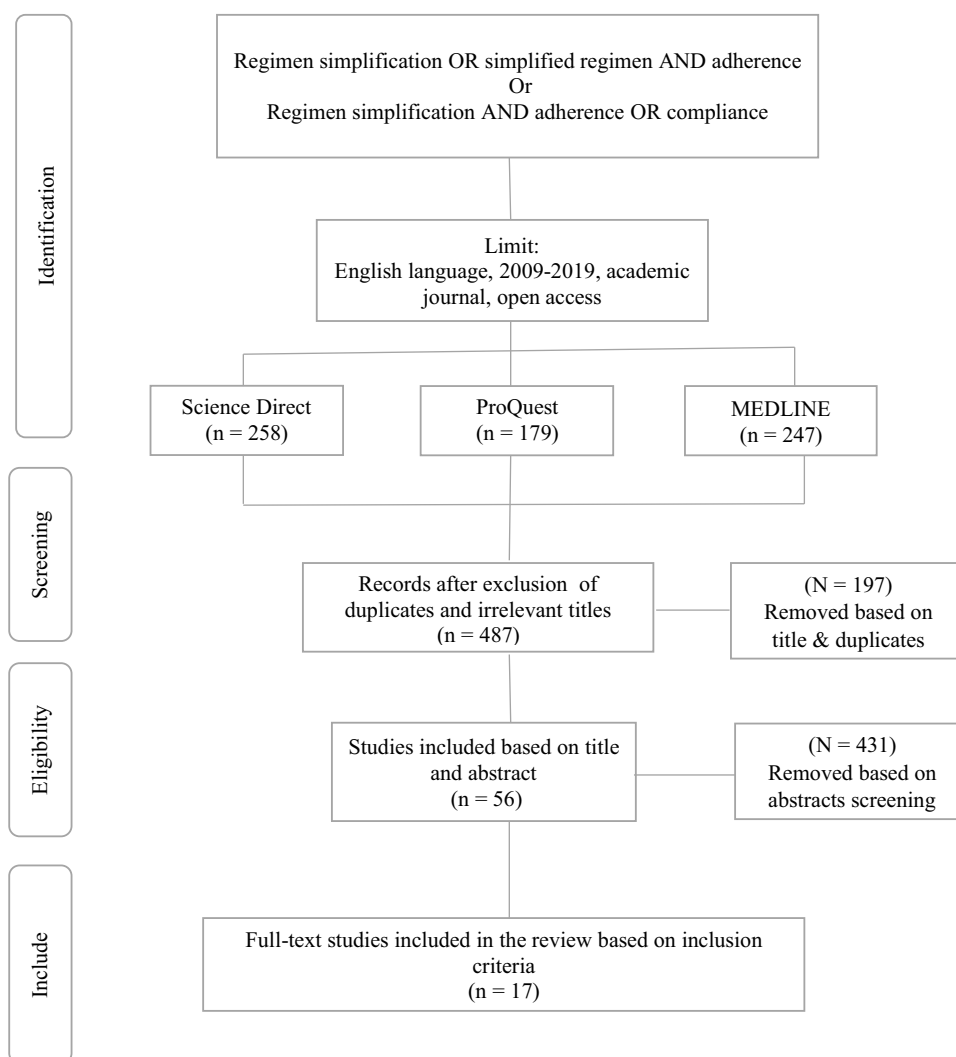

Figure 1 The process of identification, screening, and inclusion of papers for this review.

studies (53%) investigated the simplification of medication regimen in HIV patients,^{6,15–22} and three studies (18%) involved medication simplification among patients with type 2 diabetes mellitus with or without coronary artery disease (CAD).^{7,23,24} The remaining five studies (29%) included patients with different conditions such as venous thromboembolism (VTE), psychiatric disorder, glaucoma, kidney transplant and residents of aged care facilities.^{10,13,14,25,26} Almost all the studies reported direct measures of adherence except three studies that reported the potential improvement of adherence as a result of decreasing treatment burden,²³ increase medication exposure,²⁴ and reduce the time of medication administration.²⁶ Thirteen of the seventeen studies reported clinical outcomes associated with the simplification of drug regimen, while four studies reported adherence measures with no clinical outcomes. Table 1 shows the characteristics of the studies that focused

on the simplification of antiretroviral therapy (ART) regimens.

Simplification of Drug Regimens in Chronic Medical Conditions

Nine studies were identified that reported on simplification of ART drug regimens. Of these, four were conducted in the US,^{6,16,17,21} two in Spain,^{15,19} and one each in Italy, Brazil and Malaysia.^{18,20,22} Three of the studies were randomized trials,^{17,20,21} four retrospective studies^{6,18,19,22} while two were prospective cohort analyses.^{15,16} In six studies, medication regimen simplification improved medication adherence.^{6,15,18,20–22} One study did not assess the clinical outcomes associated with regimen simplification.¹⁹ On the other hand, eight studies were identified that reported on the simplification

Table 1 Studies That Reported Simplification of Drug Regimens (N=17)

Author and Country	Study Design	Study Population	Objectives/Rationale
Angela et al 2010 ⁶ USA	Retrospective cohort study involved	75 patients on ARV regimens.	Examine the impact of pharmacist's intervention on adherence and clinical outcomes of ARV regimens.
Rubio et al 2010 ¹⁵ Spain	Prospective cohort study	183 HIV-infected patients on protease inhibitors (PIs) therapy.	Determine the effectiveness and adherence and of simplified once-daily dosing of atazanavir boosted with ritonavir (ATV/r).
Buscher et al 2012 ¹⁶ USA	Prospective cohort study	99 newly diagnosed HIV patients.	To determine the effect of ART dosing frequency and number of pills on the adherence of newly diagnosed HIV patients.
Pallela et al 2014 ¹⁷ USA	Randomized open-label trial	476 HIV-I RNA suppressed patients	To examine the efficacy of antiretroviral simplification from a ritonavir-boosted protease inhibitor therapy (NRTI) to STR.
Fabbiani et al 2014 ¹⁸ Italy	Retrospective cohort study	553 patients on EFV containing regimens.	Determine the risk of therapy interruption of STR compared to BID or OD EFV therapy.
Arroyo et al 2016 ¹⁹ Spain	Retrospective study	264 patients on ART treatment	Evaluate the influence of the number of daily pills and daily doses on treatment adherence in a 7-year pharmaceutical care program.
Velvanathan et al 2016 ²⁰ Malaysia	Randomized control trial.	120 of HIV patients	Compare the clinical outcomes, adherence of patients on FDC vs FRC containing emtricitabine (FTC), tenofovir (TDF), and efavirenz (EFV).
Chen et al 2017 ²¹ USA	Randomized control trial	Involved 750 HIV patients.	To assess adherence barriers in correlation with STR, single-dose MTR, and multi-dose MTR of ART.
Laliberte' et al 2013 ¹⁴ USA	Retrospective cohort study	5756 patients with venous thromboembolism (VTE).	Evaluate the adherence rates between OD and BID chronic medication regimens for DM and HTN in patients with VTE.
Stange et al 2013 ⁷ Germany	Prospective, semi-randomized trial	240 adult inpatients with HTN, DM, and/or dyslipidemia.	To examine the impact of structured pharmacist's intervention on healthcare providers on reducing the complexity of the medication regimen.
Pauly et al 2015 ¹⁰ Germany	Prospective open clinical trial	269 psychiatric patients.	Assess the effect of multi-dimensional interventions in improving adherence to complex regimen therapy.
Barnebey & Robin 2017 ¹³ USA	Randomised controlled trial	81 adult patients diagnosed with open-angle glaucoma or ocular hypertension.	To assess the adherence of TTFC with unfixed agents of travoprost and timolol (TRAV+ TIM).
Taybani et al 2019 ²³ Hungary	Prospective single-arm clinical trial	62 patients with T2DM.	Assess the impact of switching insulin therapy from MDI to the once-daily fixed-ratio combination.
Oh C.K et al 2020 ²⁵ South Korea	Prospective cohort trial	160 kidney transplant recipients.	Evaluate the medication adherence of tacrolimus, sirolimus, and corticosteroids as a simplified once-daily immunosuppressive regimen.

Table 1 (Continued).

Author and Country	Study Design	Study Population	Objectives/Rationale
Dudl et al 2009 ²⁴ USA	Three-year observational study	170,024 patients with diabetes, CAD, or both.	To assess the effect of promoting a bundle of fixed doses of a generic statin and angiotensin-converting enzyme inhibitor/angiotensin receptor blocker (ACEI/ARB),
Sluggett et al 2020 ²⁶ Australia	Pre-planned secondary analysis of a cluster randomized controlled trial	242 residents of eight residential aged care facilities (simplification was done for 62 residents in interventional arm)	To evaluate the impact of a medication regimen simplification on medication administration times, falls, hospitalization and mortality at 12 months follow up.
S.F Dos Santos et al ²² 2020 Brazil	Retrospective cohort study	1206 patients using MTR of efavirenz, tenofovir and lamivudine who switched to the STR.	To evaluate the impact of switching from MTR to STR on adherence to cART.

of drug regimens related to other medical conditions. These included three that were conducted in the US,^{13,14,24} two in Germany,^{7,10} and one each in Hungary, Australia and South Korea.^{23,25,26} There were four prospective clinical trials,^{7,10,23,25} two randomized trials,^{13,26} and two retrospective cohort studies.^{14,24} Three of the studies (3/8) in this category did not assess the clinical outcomes associated with regimen simplifications.

Impact of Simplification Strategies on Outcome Measures

With regards to ART regimens, a single-tablet regimen and fixed-dose combination were reported in five studies.^{17,18,20–22} Two studies simplified the medication regimen using once-daily dosing.^{15,16} Another two studies considered simplification by reducing both the number and frequency of given medications.^{6,19} Regarding the simplification for regimens other than ART regimens, four studies simplified regimen by adopting a single approach.^{13,14,24,25} Whereas in the other four studies, mixed simplification strategies were implemented.^{7,10,23,26} Table 2 provides an overview of the simplification strategies for regimens of different conditions and their impact on outcome measures.

Discussion

In a recent meta-analysis, the association between the degree of medication complexity and the clinical outcomes of hospitalisation, hospital readmission and medication non-adherence

across different studies has been reported.²⁷ Furthermore, a recent systematic review on the medication adherence interventions highlighted the need to focus on the interventions that deemed to be effective to improve adherence such as medication regimen simplification, education and reminders.²⁸ However, to the author's knowledge, this is the first study that has assessed the impact of medicine regimen simplification strategies on medicine adherence and clinical outcomes in patients with long-term medical conditions. This study identified three strategies that were used to reduce the complexity of medication regimens; fixed-dose combination, once-daily dosing and a combination of more than one approach. Overall, most of the regimen simplification strategies were found to be useful in improving medicine adherence. Although it can be expected that improving medicine adherence would positively impact clinical outcomes, the findings of this study suggest that clinical outcomes were not consistently enhanced by regimen simplification in a pattern that is consistent with an improvement in medicine adherence.

Fixed Dosed Combination/Single Tablet Regimen

The medication regimen factors such as the dosing frequency and the degree of medication regimen complexity have been highlighted as factors affecting medication adherence among patients on chronic therapies.²⁹ Moreover, in a recent systematic review that investigated the association between medication regimen complexity and adherence to the prescribed pharmacotherapy, a decrease in medication adherence was observed

Table 2 Simplification Strategies of Drug Regimens and Its Impact on Outcome Measures (N=17)

Author and Country	Simplification Strategy	Outcome Measures (Adherence)	Outcome Measures (Clinical)	Impact on Outcomes
Angela et al 2010 ⁶ USA	Reducing pill burden and dosing frequency	Refill records	CD4 count	Increase treatment adherence and improve clinical outcomes.
Rubio et al 2010 ¹⁵ Spain	Once-daily dosing	Self-reported	Assessment of virological failure	Retained virological response with a slight improvement in adherence.
Buscher et al 2012 ¹⁶ USA	Once-daily dosing	Visual analogue scale.	Assessment of treatment failure (HIV-RNA levels)	Greater adherence with no difference in clinical outcomes.
Palella et al 2014 ¹⁷ USA	Single tablet regimen	Visual analogue scale.	Virological suppression	Maintained virological suppression. No difference in adherence.
Fabbiani et al 2014 ¹⁸ Italy	Single tablet regimen	Treatment discontinuation	Virological suppression	Higher adherence and lower virological failure
Arroyo et al 2016 ¹⁹ Spain	Reducing daily doses and pills	Dispensing records	No assessment	Higher adherence levels.
Velvanathan et al 2016 ²⁰ Malaysia	Fixed-dose combination	Morisky scores	CD4 count	Improved clinical outcomes and patients' adherence.
Chen et al 2017 ²¹ USA	Single tablet regimen	Pill counts	CD4 count Viral load ((HIV-RNA levels)	Higher medication adherence and lower viral load
Laliberte' et al 2013 ¹⁴ USA	Once-daily dosing	MPR and PDC > 80%	No assessment	Higher adherence
Stange et al 2013 ⁷ Germany	Reducing the number and frequency of medications	Self-reported MARS-D	No assessment	No significant change in adherence.
Pauly et al 2015 ¹⁰ Germany	Decrease dosing frequency Discontinue unnecessary drugs	MARS	No assessment	Enhanced adherence
Barnebey and Robin 2017 ¹³ USA	Fixed-dose combination	Dosing aid records	IOP reduction	Better adherence. IOP reductions were similar.
Taybani et al 2019 ²³ Hungary	Once-daily dosing Fixed-dose combination	Indirect (decrease treatment burden)	HbA1c level Glycaemic control	Effective decreased treatment burden and may improve adherence to therapy.
Oh C.K et al 2020 ²⁵ South Korea	Once-daily dosing	Self-reported (TBS scores)	Biopsy confirmed acute rejection (BCAR)	Improved adherence without risk of treatment failure.

(Continued)

Table 2 (Continued).

Author and Country	Simplification Strategy	Outcome Measures (Adherence)	Outcome Measures (Clinical)	Impact on Outcomes
Dudl et al 2009 ²⁴ USA	Fixed-dose combination	Indirect (medication bundle exposure)	Risk of hospitalization for MI or stroke in the following year.	Higher medication exposure and decreased risk of MI or stroke hospitalization.
Sluggett et al 2020 ²⁶ Australia	Long-acting and combination formulations	Indirect (reduce times of medication administration)	Risk of falls, hospitalization, and mortality.	Significant reduction of medication administration times. Higher risk of falls. No significant differences were observed for risk of hospitalization or mortality.
Dos Santos et al 2020 ²² Brazil	Single tablet regimen	Proportion of days covered (PDC≥95%)	Viral load	Significant increase in adherence levels with no difference in viral load outcomes

with the increase in medication regimen complexity.³⁰ Therefore, interventions to simplify the prescribed regimens in either dose or frequency were thought to be helpful to show a favourable impact on overall medication adherence among a wide range of patients with chronic conditions such as epilepsy, schizophrenia, dyslipidemia, hypertension, diabetes and HIV.^{31–36} The importance of medication adherence in HIV patients cannot be overemphasized. Non-adherence to ART treatment would lead to resistance and treatment failure.²¹ Therefore, it is crucial to ensure that HIV-infected patients comply with their treatment appropriately. Fixed dosed combination (FDC) combines more than a single agent in one formulation and this generally reduces the number of pills to be consumed, consequently eliminating the need to administer multiple medications.

Our work demonstrated that there was considerable work on medication regimen simplifications for patients with HIV compared to all other chronic conditions. In this review, FDC was used in seven studies and five of them involved ART regimens. In a study conducted in the US that involved HIV patients, the simplification of the regimen had no impact on adherence; however, it showed similar effectiveness compared to the conventional regimen.¹⁷ One possible reason for the lack of effect on adherence could be the use of a visual analogue scale (VAS) to measure adherence. Finitsis et al highlighted that VAS as a measure for adherence had a small association with clinical outcomes and needs further methodological verification.³⁷

On the contrary, an Italian study reported that a simplified ART regimen was associated with less treatment interruption and better effectiveness.¹⁸ Similarly, in a recent US study,

a simplified regimen of ART therapy involving Single-Tablet Regimen (STR) was reported to be associated with higher adherence levels and better clinical outcomes.²¹ In addition, a study conducted in Malaysia also reported that the FDC of the ART regimen was associated with an increase in clinical outcomes and adherence levels.²⁰ In the context of ART regimens, convenient methods that reduce the number of daily pills increased medicine adherence and improved clinical outcomes. It is essential to highlight that the primary aim of most of the studies was to provide a more convenient therapeutic option that could at least maintain the same level of viral suppression. However, some studies reported improvement in clinical outcomes, in addition to an increase in adherence levels.^{18,20,21}

Apart from ART regimens, a study conducted by Barnebey et al reported a significant increase in adherence after simplifying ophthalmology eye drops for glaucoma using a fixed-dose combination. However, there was no significant difference in clinical outcomes.¹³ Besides, previous studies also discussed the use of FDC glyburide-metformin as a simplification strategy for diabetic patients in one single fixed combination to lessen the pill requirement, reduce treatment complexity and increase patients' adherence.^{38,39} Furthermore, studies that compared the adherence rate of FDC amlodipine-benazepril with the corresponding free-drug combinations in hypertensive patients, showed higher adherence in the former.^{40,41} It is therefore noticeable that the use of a fixed-dose combination is more reported in the context of simplifying the ART regimens with a high probability of improving adherence and at least maintain the same clinical outcomes. Furthermore, it seems to be a reasonable simplification strategy in a range of

other medical conditions that require regular use of multiple medications such as diabetes, hypertension and glaucoma.

Once-Daily Dosing

The once-daily (OD) dosing frequency is an approach that reduces regimen complexity with evidence showing a higher adherence rate with OD dosing.^{14,19,25,42,43} In a metanalysis conducted to investigate the impact of dosing frequency on the medication adherence among patients with chronic CVD, the findings showed that approximately the once-daily dosing of the prescribed pharmacotherapy was associated with 50% decrease in the non-adherence risk although the impact on clinical outcomes was not well established.⁴⁴ The approach of simplifying medication using the OD dosing regimen was identified in four included studies. In a Spanish study, it was observed that simplification to once-daily dosing ART regimen was associated with better clinical outcomes and with slight variation in the self-reported adherence.¹⁵ In contrast, Buscher et al showed that a simplified once-daily ART regimen had no impact on clinical outcomes despite the improvement in the adherence measured by VAS.¹⁶ On the other contrary, a US study that investigated the impact of OD simplification on the adherence to hypertensive and anti-diabetic medications reported a positive effect on medicine adherence.¹⁴ In this study, there was no assessment for clinical outcomes. Furthermore, in a study aimed at simplifying immunosuppressant regimens for kidney transplant patients, it was found that OD simplified regimens were associated with a higher level of self-reported adherence with no risk of treatment failure.²⁵

Similarly, a study involving anti-asthmatic medications carried out by Kuna et al⁴³ in 2005 showed a greater impact of adherence on the maintenance therapy of OD budesonide-formoterol due to its convenient administration. The OD dosing may specifically be appropriate for patients with mild asthma who are reported to neglect their maintenance therapy during the symptom-free period.⁴³ After all, simplified dosing frequency does influence a patient's compliance with long-term medication therapy.

Combination of More Than One Simplification Strategy

In six studies, the simplification strategies used a combination of both decreasing the pills burden and dosing frequency. It has been reported that both adherence and clinical outcomes are enhanced following the simplification of the ART regimen.⁶ Similar findings for adherence have also been reported by researchers in Spain.¹⁹

Concerning oral diabetic and hypertensive medications, a combined simplification strategy was not associated with a noticeable impact on adherence.⁷ However, the combined simplification intervention was associated with improvement in adherence with regards to injectable insulins.²³ Similar positive impact on adherence to antipsychotic medications was also reported in a German study that used a combined simplification strategy.¹⁰

Interestingly, a study that showed the effect of OD dosing of ART regimen on adherence, the researcher did compare it to a fixed-dose combination of this OD dosing but failed to show any noticeable difference.¹⁶ It is important to highlight that the implemented simplification strategy to enhance the adherence among psychiatric patients was part of multidimensional interventions including counselling and comprehensive medication review. Overall, in this category, the adherence levels were most likely to be improved, but the clinical outcomes were not reported or experienced modest improvement.

In a recent Australian study that involved an overall eight aged care facilities, the simplification was adopted mainly through the use of long-acting and combination regimens where available.²⁶ Unlike other studies that had a medication or regimen in the focus of the simplification, this Australian study was introducing the simplification as a feasible approach to be followed to decrease the medications burden as long as the alternatives were available. We acknowledge that the improvement of medication adherence among elderly individuals is modulated by a broad spectrum of educational, behavioural factors besides the interventions that could be initiated and managed through the healthcare providers.⁴⁵ Among those interventions that could be initiated by healthcare providers, medication regimen simplification was found to be a feasible and effective strategy, however, it requires further training and time allocation for better outcomes.⁴

The Overall Impact of Regimen Simplification on Adherence and Clinical Outcomes

Across all the seventeen studies included in this review, three studies reported no significant impact on adherence following regimen simplification.^{7,15,17} Noticeably in these three studies, the assessment of adherence was predominantly self-reported. However, future studies should be consistent in the use of quantitative measures for assessing

medicine adherence to determine the actual impact on adherence following regimen simplification strategies.

Unlike adherence, the impact of regimen simplification on clinical outcomes was not conclusive because of the lack of assessment of the clinical outcomes in four of the included studies.^{7,10,14,19} In addition, more than half of the remaining studies showed that the simplified regimens demonstrated the same clinical outcomes as compared to conventional regimens. It can, therefore, be concluded that there is relatively little evidence to support that regimen simplifications improve clinical outcomes. This finding was consistent with a previously conducted meta-analysis that showed that simplification the prescribed pharmacotherapy was not consistently linked to improvement in clinical outcomes despite its positive impact on medication adherence.⁴⁴

In a recent Jordanian study among patients with osteoporosis, it has been observed that the medication non-adherence was affected by the increased number of prescribed medications.⁴⁶ Therefore, a simplified regimen possibly with STR or fixed-dose combination might provide a reasonable clinical solution to improve adherence. Moreover, a meta-analysis by Igaly et al has indicated that once-weekly dosing of treatment for osteoporosis was associated with better adherence levels and higher odds of being adherent as compared to the once-daily dosing.⁴⁷

It is important to highlight that simplification of medication regimens does not necessarily need to be designed as interventions to address problems of non-adherence. Instead, it can be considered an approach followed by the healthcare providers to initiate, change and individualise the therapeutic choices to be more likely encouraging patient compliance to the anticipated medication-taking behaviours.⁴⁸ Also, previous evidence has highlighted that the interventions considering other educational and behavioural aspects in addition to the interventions initiated by healthcare providers will more likely to have a relatively sustained impact on medication adherence.⁴⁵ There is sufficient evidence to support that the pharmacist being one of the primary healthcare providers responsible for improving medication adherence,⁴⁹ is expected to play a crucial role in initiating and applying feasible interventions for medication regimen simplifications.^{4,26}

This study has some limitations. Quality assessment of the included studies was not conducted. The searches were restricted to three databases that may have limited the opportunity to identify further eligible studies published in other relevant databases. Furthermore, since the study was limited to the inclusion of published literature only, publication bias is probable.

Conclusion

This review identified three main strategies used for regimen simplifications; fixed-dose combination, once-daily dosing, and a combination of both fixed-dose combination and once-daily dosing. Overall, the strategies were found to be useful and feasible to improve medication adherence. However, clinical outcomes were not consistently improved by regimen simplification interventions in a pattern that is consistent with the increase in adherence. Future work may be directed at refining the use of feasible streamlined drug regimens with a greater emphasis on the impact on clinical outcomes.

Patient Preference and Adherence

Dovepress

Publish your work in this journal

Patient Preference and Adherence is an international, peer-reviewed, open access journal that focusing on the growing importance of patient preference and adherence throughout the therapeutic continuum. Patient satisfaction, acceptability, quality of life, compliance, persistence and their role in developing new therapeutic modalities and compounds to optimize clinical outcomes for existing disease

states are major areas of interest for the journal. This journal has been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
